1. Problem Statement

Interactive Gaming Challenges

Standard text-based games lack dynamic interaction between human players and computer opponents, missing real-time competitive elements and robust validation.

The Solution: Number Guessing Race

A turn-based interactive race where you compete head-to-head against the computer to guess a secret number first, utilizing loops, conditionals, and input validation.

2. Objectives

- ✓ **Turn-Based Competition:** Implement a competitive gameplay loop between user and computer.
- ✓ **Control Flow:** Master practical application of `while` and `for` loops.
- ✓ **Conditional Logic:** Utilize `if/elif/else` branches to give high/low hints.
- ✓ **Input Validation:** Ensure program resilience against invalid user entries.

3. Algorithm

Initialization

1. Start the game & import random module.
2. Generate a random secret number within a specified range (e.g., 1 to 100).
3. Initialize attempt counters for both player and computer.

Execution Loop

4. Accept validated user input guess.
5. Generate automated computer guess.
6. Compare guesses against secret number using conditional branches.
7. Declare winner upon matching the secret number.

4. Understanding Python Logic

```
# Secret Number Generation & Loop
import random
secret = random.randint(1, 100)
running = True

while running:
    guess = int(input("Enter guess: "))
    if guess == secret:
        print("You Win!")
        break
    elif guess < secret:
        print("Too low!")
    else:
        print("Too high!")
```

Core Constructs

Loops: Controls continuous turns until a match occurs.

Conditionals: Evaluates relationship between guess and secret number.

Validation: Catches non-numeric inputs gracefully.

5. Game Flow & Working

Player Turn

User inputs a guess. The program validates input type, compares against the secret target, and outputs feedback ("Too High" or "Too Low").

Computer Turn

Computer uses smart boundary adjustments (binary search logic) to make optimal guesses, creating a genuine race atmosphere.

6. GitHub & Collaboration

Repository Management

- Created dedicated public repository: Number - Guessing - Race
- Organized folder structure and documented README instructions.

Version Control

- Meaningful commits for feature additions.
- Branching workflows and collaborative pull requests used effectively by team members.

7. Individual Contribution

Logic Design: Designed the turn-based state machine and validation functions.

Python Coding: Developed core gameplay loops and computer AI guessing heuristics.

Testing & Debugging: Verified edge cases like out-of-range inputs and string entries.

Documentation: Prepared presentation deck and repository documentation.

8. Result / Expected Output

```
=== NUMBER GUESSING RACE ===  
Secret number chosen between 1 and 50.
```

```
Your turn! Enter your guess: 25  
-> Too low! Try a higher number.
```

```
Computer's turn... Computer guesses: 37  
-> Too high!
```

```
Your turn! Enter your guess: 31  
-> Correct! You won the race!
```

Output Highlights

- Instant feedback on every attempt.
- Clear turn alternation between user and computer.
- Accurate victory detection and termination.

Thank You!
